

FEATURES

- 2.5 kV fully isolated (power and data) RS-232 transceiver
- isoPower* integrated, isolated dc-to-dc converter
- 460 kbps data rate
- 1 Tx and 1 Rx
- Meets EIA/TIA-232E specifications
- ESD protection on R_{IN} and T_{OUT} pins
 - ±8 kV: contact discharge
 - ±15 kV: air gap discharge
- 0.1 μF charge pump capacitors
- High common-mode transient immunity: >25 kV/μs
- Safety and regulatory approvals
 - UL recognition
 - 2500 V rms for 1 minute per UL 1577
 - VDE Certificate of Conformity
 - DIN EN 60747-5-2 (VDE 0884 Teil 2): 2003-01
 - CSA Component Acceptance Notice #5A
- Operating temperature range: -40°C to +85°C
- Wide body, 20-lead SOIC package

APPLICATIONS

- High noise data communications
- Industrial communications
- General-purpose RS-232 data links
- Industrial/telecommunications diagnostic ports
- Medical equipment

GENERAL DESCRIPTION

The ADM3251E is a high speed, 2.5 kV fully isolated, single-channel RS-232/V.28 transceiver device that operates from a single 5 V power supply. Due to the high ESD protection on the R_{IN} and T_{OUT} pins, the device is ideally suited for operation in electrically harsh environments or where RS-232 cables are frequently being plugged and unplugged.

The ADM3251E incorporates dual-channel digital isolators with *isoPower*™ integrated, isolated power. There is no requirement to use a separate isolated dc-to-dc converter. Chip-scale transformer *iCoupler*® technology from Analog Devices, Inc., is used both for the isolation of the logic signals as well as for the integrated dc-to-dc converter. The result is a total isolation solution.

The ADM3251E contains *isoPower* technology that uses high frequency switching elements to transfer power through the

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

transformer. Special care must be taken during printed circuit board (PCB) layout to meet emissions standards. Refer to Application Note AN-0971, *Control of Radiated Emissions with isoPower Devices*, for details on board layout considerations.

The ADM3251E conforms to the EIA/TIA-232E and ITU-T V.28 specifications and operates at data rates up to 460 kbps.

Four external 0.1 μF charge pump capacitors are used for the voltage doubler/inverter, permitting operation from a single 5 V supply.

The ADM3251E is available in a 20-lead, wide body SOIC package and is specified over the -40°C to +85°C temperature range.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

ADM3251E

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

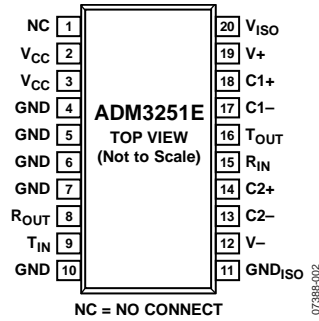

Figure 2. Pin Configuration

Table 8. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	NC	No Connect. This pin should always remain unconnected.
2, 3	V _{CC}	Power Supply Input. A 0.1 μF decoupling capacitor is required between V _{CC} and ground. When a voltage between 4.5 V and 5.5 V is applied to the V _{CC} pin, the integrated dc-to-dc converter is enabled. If this voltage is lowered to between 3.0 V and 3.7 V, the integrated dc-to-dc converter is disabled.
4, 5, 6, 7, 10	GND	Ground.
8	R _{OUT}	Receiver Output. This pin outputs CMOS logic levels.
9	T _{IN}	Transmitter (Driver) Input. This pin accepts TTL/CMOS levels.
11	GND _{ISO}	Ground Reference for Isolator Primary Side.
12	V ₋	Internally Generated Negative Supply.
13, 14	C2 ₋ , C2 ₊	Positive and Negative Connections for Charge Pump Capacitors. External Capacitor C2 is connected between these pins; a 0.1 μF capacitor is recommended, but larger capacitors up to 10 μF can be used.
15	R _{IN}	Receiver Input. This input accepts RS-232 signal levels.
16	T _{OUT}	Transmitter (Driver) Output. This outputs RS-232 signal levels.
17, 18	C1 ₋ , C1 ₊	Positive and Negative Connections for Charge Pump Capacitors. External Capacitor C1 is connected between these pins; a 0.1 μF capacitor is recommended, but larger capacitors up to 10 μF can be used.
19	V ₊	Internally Generated Positive Supply.
20	V _{ISO}	Isolated Supply Voltage for Isolator Secondary Side. A 0.1 μF decoupling capacitor is required between V _{ISO} and ground. When the integrated dc-to-dc converter is enabled, the V _{ISO} pin should not be used to power external circuitry. If the integrated dc-to-dc converter is disabled, power the secondary side by applying a voltage in the range of 3.0 V to 5.5 V to this pin.

THEORY OF OPERATION

The ADM3251E is a high speed, 2.5 kV fully isolated, single-channel RS-232 transceiver device that operates from a single power supply.

The internal circuitry consists of the following main sections:

- Isolation of power and data
- A charge pump voltage converter
- A 5.0 V logic to EIA/TIA-232E transmitter
- A EIA/TIA-232E to 5.0 V logic receiver

*INTERNAL 5kΩ PULL-DOWN RESISTOR ON THE RS-232 INPUT.

Figure 13. Functional Block Diagram

ISOLATION OF POWER AND DATA

The ADM3251E incorporates a dc-to-dc converter section, which works on principles that are common to most modern power supply designs. V_{CC} power is supplied to an oscillating circuit that switches current into a chip-scale air core transformer. Power is transferred to the secondary side, where it is rectified to a high dc voltage. The power is then linearly regulated to about 5.0 V and supplied to the secondary side data section and to the V_{ISO} pin. The V_{ISO} pin should not be used to power external circuitry.

Because the oscillator runs at a constant high frequency independent of the load, excess power is internally dissipated in the output voltage regulation process. Limited space for transformer coils and components also adds to internal power dissipation. This results in low power conversion efficiency.

The ADM3251E can be operated with the dc-to-dc converter enabled or disabled. The internal dc-to-dc converter state of the ADM3251E is controlled by the input V_{CC} voltage. In normal operating mode, V_{CC} is set between 4.5 V and 5.5 V and the internal dc-to-dc converter is enabled. To disable the dc-to-dc converter, lower V_{CC} to a value between 3.0 V and 3.7 V. In this mode, the user must externally supply isolated power to the V_{ISO} pin. An isolated secondary side voltage of between 3.0 V and 5.5 V and a secondary side input current, I_{ISO} , of 12 mA (maximum) is required on the V_{ISO} pin. The signal channels of the ADM3251E then continue to operate normally.

The T_{IN} pin accepts TTL/CMOS input levels. The driver input signal that is applied to the T_{IN} pin is referenced to logic ground (GND). It is coupled across the isolation barrier, inverted, and then appears at the transceiver section, referenced to isolated ground (GND_{ISO}). Similarly, the receiver input (R_{IN}) accepts RS-232 signal levels that are referenced to isolated ground. The R_{IN} input is inverted and coupled across the isolation barrier to appear at the R_{OUT} pin, referenced to logic ground.

The digital signals are transmitted across the isolation barrier using *iCoupler* technology. Chip-scale transformer windings couple the digital signals magnetically from one side of the barrier to the other. Digital inputs are encoded into waveforms that are capable of exciting the primary transformer of the winding. At the secondary winding, the induced waveforms are decoded into the binary value that was originally transmitted.

There is hysteresis in the V_{CC} input voltage detect circuit. Once the dc-to-dc converter is active, the input voltage must be decreased below the turn-on threshold to disable the converter. This feature ensures that the converter does not go into oscillation due to noisy input power.

Figure 14. Typical Operating Circuit with the DC-to-DC Converter Enabled ($V_{CC} = 4.5\text{ V to }5.5\text{ V}$)

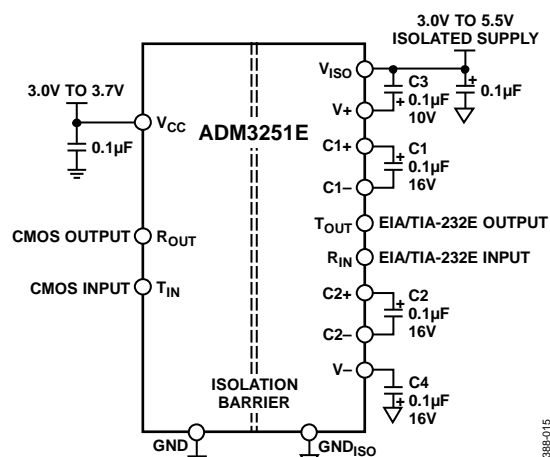

Figure 15. Typical Operating Circuit with the DC-to-DC Converter Disabled ($V_{CC} = 3.0\text{ V to }3.7\text{ V}$)

ADM3251E

CHARGE PUMP VOLTAGE CONVERTER

The charge pump voltage converter consists of a 200 kHz oscillator and a switching matrix. The converter generates a ± 10.0 V supply from the input 5.0 V level. This is done in two stages by using a switched capacitor technique as illustrated in Figure 16 and Figure 17. First, the 5.0 V input supply is doubled to 10.0 V by using C1 as the charge storage element. The +10.0 V level is then inverted to generate -10.0 V using C2 as the storage element. C3 is shown connected between $V+$ and V_{ISO} , but is equally effective if connected between $V+$ and GND_{ISO} .

Capacitor C3 and Capacitor C4 are used to reduce the output ripple. Their values are not critical and can be increased, if desired. Larger capacitors (up to 10 μ F) can be used in place of C1, C2, C3, and C4.

5.0 V LOGIC TO EIA/TIA-232E TRANSMITTER

The transmitter driver converts the 5.0 V logic input levels into RS-232 output levels. When driving an RS-232 load with $V_{CC} = 5.0$ V, the output voltage swing is typically ± 10 V.

Figure 16. Charge Pump Voltage Doubler

Figure 17. Charge Pump Voltage Inverter

EIA/TIA-232E TO 5 V LOGIC RECEIVER

The receiver is an inverting level-shifter that accepts the RS-232 input level and translates it into a 5.0 V logic output level. The input has an internal 5 k Ω pull-down resistor to ground and is also protected against overvoltages of up to ± 30 V. An unconnected input is pulled to 0 V by the internal 5 k Ω pull-down resistor. This, therefore, results in a Logic 1 output level for an unconnected input or for an input connected to GND. The receiver has a Schmitt-trigger input with a hysteresis level of 0.1 V. This ensures error-free reception for both a noisy input and for an input with slow transition times.

HIGH BAUD RATE

The ADM3251E offers high slew rates, permitting data transmission at rates well in excess of the EIA/TIA-232E specifications. The RS-232 voltage levels are maintained at data rates up to 460 kbps.

THERMAL ANALYSIS

Each ADM3251E device consists of three internal die, attached to a split-paddle lead frame. For the purposes of thermal analysis, it is treated as a thermal unit with the highest junction temperature reflected in the θ_{JA} value from Table 7. The value of θ_{JA} is based on measurements taken with the part mounted on a JEDEC standard 4-layer PCB with fine-width traces in still air. Following the recommendations in the PCB Layout section decreases the thermal resistance to the PCB, allowing increased thermal margin at high ambient temperatures.

INSULATION LIFETIME

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation. In addition to the testing performed by the regulatory agencies, Analog Devices carries out an extensive set of evaluations to determine the lifetime of the insulation structure within the ADM3251E.

The insulation lifetime of the ADM3251E depends on the voltage waveform type imposed across the isolation barrier. The *iCoupler* insulation structure degrades at different rates depending on whether the waveform is bipolar ac, unipolar ac, or dc. Figure 18, Figure 19, and Figure 20 illustrate these different isolation voltage waveforms.

Bipolar ac voltage is the most stringent environment. In the case of unipolar ac or dc voltage, the stress on the insulation is significantly lower.

APPLICATIONS INFORMATION

PCB LAYOUT

The ADM3251E requires no external circuitry for its logic interfaces. Power supply bypassing is required at the input and output supply pins (see Figure 21). Bypass capacitors are conveniently connected between Pin 3 and Pin 4 for V_{CC} and between Pin 19 and Pin 20 for V_{ISO} . The capacitor value should be between $0.01 \mu\text{F}$ and $0.1 \mu\text{F}$. The total lead length between both ends of the capacitor and the input power supply pin should not exceed 20 mm.

Because it is not possible to apply a heat sink to an isolation device, the device primarily depends on heat dissipating into the PCB through the ground pins. If the device is used at high ambient temperatures, care should be taken to provide a thermal path from the ground pins to the PCB ground plane. The board layout in Figure 21 shows enlarged pads for Pin 4, Pin 5, Pin 6, Pin 7, Pin 10, and Pin 11. Multiple vias should be implemented from each of the pads to the ground plane, which significantly reduce the temperatures inside the chip. The dimensions of the expanded pads are left to the discretion of the designer and the available board space.

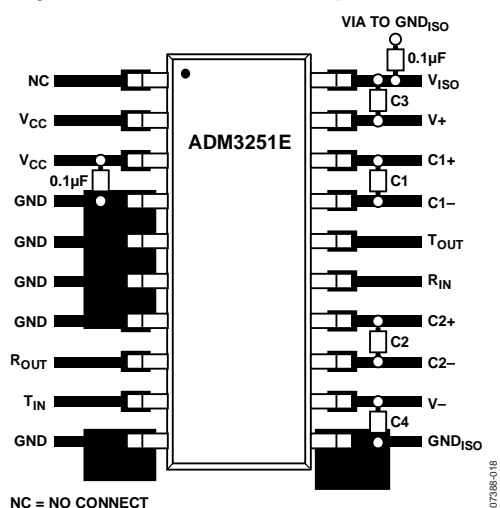

Figure 21. Recommended Printed Circuit Board Layout

In applications involving high common-mode transients, care should be taken to ensure that board coupling across the isolation barrier is minimized. Furthermore, the board layout should be designed such that any coupling that does occur equally affects all pins on a given component side.

The power supply section of the ADM3251E uses a 300 MHz oscillator frequency to pass power through its chip-scale transformers. Operation at these high frequencies may raise concerns about radiated emissions and conducted noise. PCB layout and construction is a very important tool for controlling radiated emissions. Refer to Application Note AN-0971, *Control of Radiated Emissions with isoPower Devices*, for extensive guidance on radiation mechanisms and board layout considerations.

EXAMPLE PCB FOR REDUCED EMI

The choice of how aggressively EMI must be addressed for a design to pass emissions levels depends on the requirements of the design as well as cost and performance trade-offs.

The starting point for this example is a 2-layer PCB. EMI reductions are relative to the emissions and noise from this board. To conform to FCC Class B levels, the emissions at these two frequencies must be less than $46 \text{ dB}\mu\text{V/m}$, normalized to 3 m antenna distance. As expected, EMI testing confirmed that the largest emissions peaks occur at the tank frequency and rectifier frequency.

A 6-layer PCB that employs edge guarding and buried capacitive bypassing, which are EMI mitigation techniques described in detail in Application Note AN-0971, was manufactured. The stackup of the 6-layer test PCB is shown in Table 9. PCB layout Gerber files are available upon request.

Table 9. PCB Layers

Layer	Description
Top	Components and ground planes
Inner Layer 1	V_{CC} planes
Inner Layer 2	All tracks
Inner Layer 3	Blank
Inner Layer 4	Buried capacitive plane
Bottom	Ground planes

EMI testing was repeated on the optimized board. The resulting reduction in radiated emissions is shown in Table 10. This board meets FCC Class B standards with no external shielding by utilizing buried stitching capacitors and edge fencing.

Table 10. EMI Test Results

EMI Test Results	300 MHz	600 MHz
2-Layer PCB Emissions	48 dB	53 dB
6-Layer PCB Emissions	36 dB	32 dB
Achieved EMI Reduction	12 dB	21 dB

OUTLINE DIMENSIONS
